TITLE

Peptide Inhibitors of Hepatitis C Virus NS3 Protease

FIELD OF THE INVENTION

The present invention relates generally to a novel class of peptides, which are useful as serine protease inhibitors, and more particularly as Hepatitis C virus (HCV) NS3 protease inhibitors. This invention also relates to pharmaceutical compositions comprising these compounds and methods of using the same in the treatment of HCV infection.

BACKGROUND OF THE INVENTION

Hepatitis C virus is the major cause of transfusion and community-acquired non-A, non-B hepatitis worldwide. Approximately 2% of the world's population are infected with the virus. In the Unites States, hepatitis C represents approximately 20% of cases of acute hepatitis. Unfortunately, self-limited hepatitis is not the most common course of acute HCV infection. In the majority of patients, symptoms of acute hepatitis resolve, but alanine aminotransferase (a liver enzyme diagnostic for liver damage) levels often remain elevated and HCV RNA persists. Indeed, a propensity to chronicity is the most distinguishing characteristic of hepatitis C, occurring in at least 85% of patients with acute HCV infection. The factors that lead to chronicity in hepatitis C are not well defined. Chronic HCV infection is associated with increased incidence of liver cirrhosis and liver cancer. No vaccines are available for this virus, and current treatment is restricted to the use of alpha interferon, which is effective in only 15-20% of patients. Recent clinical studies have shown that combination therapy of alpha interferon and ribavirin leads to sustained efficacy in 40% of patients (Poynard, T. et al. *Lancet* (1998), 352, 1426-1432.). However, a majority of patients still either fail

to respond or relapse after completion of therapy. Thus, there is a clear need to develop more effective therapeutics for treatment of HCV-associated hepatitis.

HCV is a positive-stranded RNA virus. Based on comparison of deduced amino acid sequence and the extensive similarity in the 5′ untranslated region, HCV has been classified as a separate genus in the Flaviviridae family, which also includes flaviviruses such as yellow fever virus and animal pestiviruses like bovine viral diarrhea virus and swine fever virus. All members of the Flaviviridae family have enveloped virions that contain a positive stranded RNA genome encoding all known virus-specific proteins via translation of a single, uninterrupted, open reading frame.

Considerable heterogeneity is found within the nucleotide and encoded amino acid sequence throughout the HCV genome. At least six major genotypes have been characterized, and more than 50 subtypes have been described. The major genotypes of HCV differ in their distribution worldwide, and the clinical significance of the genetic heterogeneity of HCV remains elusive despite numerous studies of the possible effect of genotypes on pathogenesis and therapy.

The RNA genome is about 9.6 Kb in length, and encodes a single polypeptide of about 3000 amino acids. The 5′ untranslated region contains an internal ribosome entry site (IRES), which directs cellular ribosomes to the correct AUG for initiation of translation. As was determined by transient expression of cloned HCV cDNAs, the precursor protein is cotranslationally and posttranslationally processed into at least 10 viral structural and nonstructural (NS) proteins by the action of a host signal peptidase and by two distinct viral proteinase activities. The translated product contains the following proteins: core-E1-E2-p7-NS2-NS3-NS4A-NS4B-NS5A-NS5B.

The N-terminal portion of NS3 functions as a proteolytic enzyme that is responsible for the cleavage of sites liberating the nonstructural proteins NS4A, NS4B, NS5A, and NS5B. NS3 has further been shown to be a serine protease. Although the functions of the NS proteins are not completely defined, it is known that NS4A is a protease cofactor and NS5B is an RNA polymerase involved in viral replication. Thus, agents that inhibit NS3 proteolytic processing of the viral polyprotein are expected to have antiviral activity.

Extensive efforts toward the development of HCV NS3 protease inhibitors have resulted in the following disclosures: WO 98/17679 (Tung et al.) describes a large class of generic peptide and peptidomimetic inhibitors with the following formula: $U\text{-}E^8\text{-}E^7\text{-}E^6\text{-}E^5\text{-}E^4\text{-}NH\text{-}CH(CH_2G^1)\text{-}W^1$, wherein W^1 is a variety of electrophilic groups. E4 represents either an amino acid or one of a series of peptidomimetic groups. No example of compounds wherein W^1 is boronic acid or ester is disclosed or enabled in WO 98/17679. Additionally, compounds with extended aralkyl or heteroaralkyl P1 substituents as disclosed in the present application are not disclosed, enabled or exemplified in WO 98/17679.

WO 98/22496 (Attwood et al.) discloses solely hexapeptide inhibitors of the following general formula: $R^9\text{-}NH\text{-}CH(R^8)\text{-}CO\text{-}NH\text{-}CH(R^7)\text{-}CO\text{-}N(R^6)\text{-}CH(R^5)\text{-}CO\text{-}NH\text{-}CH(R^4)\text{-}CO\text{-}N(R^3)\text{-}CH(R^2)\text{-}CO\text{-}NH\text{-}CH(R^1)\text{-}E$ wherein E is either an aldehyde or a boronic acid. Compounds with extended aralkyl or heteroaralkyl P1 substituents as disclosed in the present application are not specifically disclosed, enabled or exemplified in WO 98/22496.

WO 99/07734 (Llinas-Brunet et al.) discloses tetra- to hexa-peptide analogs containing a P_1 electrophilic carbonyl group, a phosphonate ester, or an aza-aminoacid analog. WO 99/07733 (Llinas-Brunet et al.) describes related peptides terminating in a carboxylate. Similar compounds are reported by Steinkuhler et al. *Biochemistry* (1998), 37,

8899-8905 and Ingallinella et al. *Biochemistry* (1998), 37, 8906-8914. None of these publiscations teaches the making and use of compounds with aralkyl or heteroaralkyl P1 substituents.

WO 99/50230 (Tung et al.) discloses peptidomimetics containing a 5 or 6-membered carbocyclic ring at the P2 position. Tung et al. does not teach the aralkyl or heteroaralkyl P1 substituents of the present invention.

WO 00/09543 (Llinas-Brunet et al.) discloses tripeptides containing a substituted proline residue at P2 and an aminocyclopropanecarboxylate derivative at P1. A related disclosure, WO 00/09558 (Llinas-Brunet et al.), discloses tetra- to hexapeptides with the same P1 and P2 structure as WO 00/09543.

Other peptide inhibitors of HCV protease have been disclosed. WO 98/46630 (Hart et al.) has described hepta-peptide analogs containing an ester linkage at the scissile bond. WO 97/43310 (Zhang et al.) discloses high molecular weight peptide inhibitors. The present invention is distinct from the compounds of WO 98/46630 or WO 97/43310.

Additionally, literature regarding HCV NS3 protease inhibitors suggest that the S1 pocket of the NS3 protease enzyme can only accommodate small aliphatic P1 residues. (Pizzi et al. *Proc. Natl. Acad. Sci. USA* (1994), 91, 888-892; Urbani et al. *J. Biol. Chem.* (1997) 272, 9204-9209; Perni, Robert B. *Drug News Perspective* (2000), 13, 69-77). Thus, the general literature regarding HCV NS3 protease inhibitors does not suggest or provide the motivation to one skilled in the art to make extended aralkyl P1 inhibitors of the present invention.

Based on the large number of persons currently infected with HCV and the limited treatments available, it is desirable to discover new inhibitors of HCV NS3 protease. The instant invention discloses a class of novel peptides with extended P1 residues that exhibit inhibitory activity against HCV NS3 protease. Further, the present invention discloses unexpected benefit of HCV NS3 protease

inhibitory selectivity over inhibition of elastase and/or chymotrypsin.

The compounds herein described may have asymmetric centers. All chiral, diastereomeric, and racemic forms are included in the present invention. Many geometric isomers of olefins, C=N double bonds, and the like can also be present in the compounds described herein, and all such stable isomers are contemplated in the present invention. It will be appreciated that certain compounds of the present invention contain an asymmetrically substituted carbon atom, and may be isolated in optically active or racemic forms. It is well known in the art how to prepare optically active forms, such as by resolution of racemic forms or by synthesis, from optically active starting materials. Also, it is realized that cis and trans geometric isomers of the compounds of the present invention are described and may be isolated as a mixture of isomers or as separated isomeric forms. All chiral, diastereomeric, racemic forms and all geometric isomeric forms of a structure are intended, unless the specific stereochemistry or isomer form is specifically indicated.

The reactions of the synthetic methods claimed herein are carried out in suitable solvents which may be readily selected by one skilled in the art of organic synthesis, said suitable solvents generally being any solvent which is substantially nonreactive with the starting materials (reactants), the intermediates, or products at the temperatures at which the reactions are carried out. A given reaction may be carried out in one solvent or a mixture of more than one solvent. Depending on the particular reaction step, suitable solvents for a particular reaction step may be selected.

Combinations of substituents and/or variables are permissible only if such combinations result in stable compounds. By stable compound or stable structure it is meant herein a compound that is sufficiently robust to survive isolation to a useful degree of purity from a

reaction mixture, and formulation into an efficacious therapeutic agent.

The term "substituted," as used herein, means that any one or more hydrogens on the designated atom is replaced with a selection from the indicated group, provided that the designated atom's normal valency is not exceeded, and that the substitution results in a stable compound. When a substituent is keto (i.e., =O), then two hydrogens on the atom are replaced.

When any variable (e.g., R^7 or R^{13}) occurs more than one time in any constituent or formula for a compound, its definition at each occurrence is independent of its definition at every other occurrence. Thus, for example, if a group is shown to be substituted with 0-3 R^{13}, then said group may optionally be substituted with up to three R^{13} groups and R^{13} at each occurrence is selected independently from the definition of R^{13}. Also, combinations of substituents and/or variables are permissible only if such combinations result in stable compounds. By stable compound it is meant herein a compound that is sufficiently robust to survive isolation to a useful degree of purity from a reaction mixture.

When a bond to a substituent is shown to cross a bond connecting two atoms in a ring, then such substituent may be bonded to any atom on the ring. When a substituent is listed without indicating the atom via which such substituent is bonded to the rest of the compound of a given formula, then such substituent may be bonded via any atom in such substituent. Combinations of substituents and/or variables are permissible only if such combinations result in stable compounds.

In Formula (I) the substituent A is intended to be a peptide of 2 to 6 amino acid residues. For example, the scope of A can be described as A^2-A^3, A^2-A^3-A^4, A^2-A^3-A^4-A^5, A^2-A^3-A^4-A^5-A^6, A^2-A^3-A^4-A^5-A^6-A^7. Alternatively, A can be described as $(A")_n$ wherein n is 2, 3, 4, 5, or 6. By either description when A is comprised of two amino acid

residues or greater, each amino acid residue of A is independently selected apart from each other amino acid residue. For example, A^2, A^3, A^4, A^5, A^6, and A^7 are independently selected from the defined list of possible amino acid residues, including modified or unnatural amino acid residues, disclosed herein. Likewise, each A", when n is 2 or greater, is independently selected from the defined list of possible amino acid residues, including modified or unnatural amino acid residues, disclosed herein.

"Amino acid residue" as used herein, refers to natural, modified or unnatural amino acids of either D- or L-configuration and means an organic compound containing both a basic amino group and an acidic carboxyl group. Included in the scope of the present invention are N-alkyl, aryl, and alkylaryl analogs of both in chain and N-terminal amino acid residues. Similarly, alkyl, aryl, and alkylaryl maybe substituted for the alpha hydrogen. Illustrated below are examples of N-alkyl and alpha alkyl amino acid residues, respectively.

The pharmaceutically acceptable salts include the conventional non-toxic salts or the quaternary ammonium salts of the parent compound formed, for example, from non-toxic inorganic or organic acids. For example, such conventional non-toxic salts include those derived from inorganic acids such as hydrochloric, hydrobromic, sulfuric, sulfamic, phosphoric, nitric and the like; and the salts prepared from organic acids such as acetic, propionic, succinic, glycolic, stearic, lactic, malic, tartaric, citric, ascorbic, pamoic, maleic, hydroxymaleic, phenylacetic, glutamic, benzoic, salicylic, sulfanilic, 2-acetoxybenzoic, fumaric, toluenesulfonic, methanesulfonic, ethane disulfonic, oxalic, isethionic, and the like.

<u>Scheme 1</u>

$$PG1\text{-}A^5\text{-}A^4\text{-}A^3\text{-}A^2\text{-}PG2 \xrightarrow{\text{Deprotect}} H\text{-}A^5\text{-}A^4\text{-}A^3\text{-}A^2\text{-}PG2 + PG1\text{-}A^6\text{-}OH$$

$$\xrightarrow{\text{Deprotect}} R^3\text{-}A^6\text{-}A^5\text{-}A^4\text{-}A^3\text{-}A^2\text{-}OH$$

Briefly, the A^2, A^3, and optionally A^4, A^5, and A^6 amino acids can be linked by well known peptide coupling techniques. The A^2, A^3, A^4, A^5 and A^6 moieties may be linked together in any order as long as the final compound corresponds to peptides of Formula (I). For example, A^6 can be linked to A^5 to give A^6-A^5 that is linked to A^4-A^3-A^2; or A^6 linked to A^5-A^4-A^3 then linked to an appropriately C-terminal protected A^2. Consequently, Scheme 1 enables one skilled in the art to make peptides wherein A is A^3-A^2, A^4-A^3-A^2, A^5-A^4-A^3-A^2, or A^6-A^5-A^4-A^3-A^2.

Generally, peptides are elongated by deprotecting the α-amino group of the N-terminal residue and coupling to the unprotected carboxyl group of the next suitably N-protected amino acid through a peptide linkage using the methods described. This deprotection and coupling procedure is repeated until the desired sequence is obtained. This coupling can be performed with the constituent amino acids in stepwise fashion, as depicted in Scheme 1, or by condensation of fragments (two or several amino acids), or combination of both processes, or by solid phase peptide

synthesis according to the method originally described in Merrifield, J. Am. Chem. Soc., (1963), 85, 2149-2154, the disclosure of which is hereby incorporated by reference. Coupling between two amino acids, an amino acid and a peptide, or two peptide fragments can be carried out using standard coupling procedures such as the azide method, mixed carbonic-carboxylic acid anhydride (isobutyl chloroformate) method, carbodiimide (1,3-dicyclohexylcarbodiimide, diisopropylcarbodiimide, or water-soluble carbodiimide) method, active ester (p-nitrophenyl ester, N-hydroxysuccinic imido ester) method, Woodward reagent K-method, carbonyldiimidazole method, phosphorus reagents or oxidation-reduction methods. Some of these methods (especially the carbodiimide method) can be enhanced by adding 1-hydroxybenzotriazole (HOBt) or 1-hydroxy-7-azabenzotriazole (HOAt). These coupling reactions can be performed in either solution (liquid phase) or on solid phase. More explicitly, the coupling step involves the dehydrative coupling of a free carboxyl of one reactant with the free amino group of the other reactant in the presence of a coupling agent to form a linking amide bond. Description of such coupling agents are found in general textbooks on peptide chemistry, for example, M. Bodanszky, "Peptide Chemistry", 2nd rev ed., Springer-Verlag, Berlin, Germany, (1993). Examples of suitable coupling agents are *N,N'*-1,3-dicyclohexylcarbodiimide, 1-hydroxybenzotriazole in the presence of N,N' 1,3-dicyclohexylcarbodiimide or N-ethyl-N'-[(3 dimethylamino)propyllcarbodiimide. A very practical and useful coupling agent is the commercially available (benzotriazol-1-yloxy)tris (dimethylamino)phosphonium hexafluorophosphate, either by itself or in the presence of 1-hydroxybenzotriazole. Another very practical and useful coupling agent is commercially available 2-(lH-benzotriazol-1-yl)-N, N, N', N'-tetramethyluronium tetrafluoroborate. Still another very practical and useful coupling agent is commercially available 2-(7-azabenzotriazol-1-yl) N,N,N',N'-

tetramethyluronium hexafluorophosphate. The coupling reaction is conducted in an inert solvent, e.g. dichloromethane, acetonitrile or dimethylformamide. An excess of a tertiary amine, e.g. diisopropylethylamine, N-methylmorpholine or *N*-methylpyrrolidine,or sodium bicarbonate is added to maintain the reaction mixture at a pH of about 8. The reaction temperature usually ranges between 0 °C and 50 °C and the reaction time usually ranges between 15 min and 24 h. When a solid phase synthetic approach is employed, the C-terminal carboxylic acid is attached to an insoluble carrier (usually polystyrene). These insoluble carriers contain a group that will react with the carboxylic group to form a bond that is stable to the elongation conditions but readily cleaved later. Examples of which are: chloro- or bromomethyl resin, hydroxymethyl resin, and aminomethyl resin. Many of these resins are commercially available with the desired C-terminal amino acid already incorporated. In addition to the foregoing, other methods of peptide synthesis are described in Stewart and Young, "Solid Phase Peptide Synthesis", 2 nd ed., Pierce Chemical Co., Rockford, IL (1984); Gross, Meienhofer, Udenfriend, Eds., "The Peptides: Analysis, Synthesis, Biology", Vol. 1, 2, 3, 5, and 9, Academic Press, New-York, (1980-1987); Bodansky et al., "The Practice of Peptide Synthesis" Springer-Verlag, New-York (1984), the disclosures of which are hereby incorporated by reference. The functional groups of the constituent amino acids generally must be protected during the coupling reactions to avoid formation of undesired bonds. The is protecting groups that can be used are listed in Greene, "Protective Groups in Organic Chemistry", John Wiley & Sons, New York (1981) and "The Peptides: Analysis, Synthesis, Biology", Vol. 3, Academic Press, New York (1981), the disclosures of which are hereby incorporated by reference. The α-carboxyl group of the C-terminal residue is usually protected as an ester (PG2) that can be cleaved to give the carboxylic acid. Protecting groups that can be

used include: 1) alkyl esters such as methyl, ethyl, trimethylsilylethyl and t-butyl, 2) aralkyl esters such as benzyl and substituted benzyl, or 3) esters that can be cleaved by mild base treatment or mild reductive means such as trichloroethyl and phenacyl esters. The α-amino group of each amino acid to be coupled to the growing peptide chain must be protected (PG1). Any protecting group known in the art can be used. Examples of such groups include: 1) acyl groups such as formyl, trifluoroacetyl, phthalyl, and *p*-toluenesulfonyl; 2) aromatic carbamate groups such as benzyloxycarbonyl (Cbz or Z) and substituted benzyloxycarbonyls, and 9-fluorenylmethyloxycarbonyl (Fmoc); 3) aliphatic carbamate groups such as *tert*-butyloxycarbonyl (Boc), ethoxycarbonyl, diisopropylmethoxycarbonyl, and allyloxycarbonyl; 4) cyclic alkyl carbamate groups such as cyclopentyloxycarbonyl and adamantyloxycarbonyl; 5) alkyl groups such as triphenylmethyl and benzyl; 6) trialkylsilyl such as trimethylsilyl; and 7) thiol containing groups such as phenylthiocarbonyl and dithiasuccinoyl. The preferred α-amino protecting group is either Boc or Fmoc. Many amino acid derivatives suitably protected for peptide synthesis are commercially available. The α-amino protecting group of the newly added amino acid residue is cleaved prior to the coupling of the next amino acid. When the Boc group is used, the methods of choice are trifluoroacetic acid, neat or in dichloromethane, or HCl in dioxane or in ethyl acetate. The resulting ammonium salt is then neutralized either prior to the coupling or in situ with basic solutions such as aqueous buffers, or tertiary amines in dichloromethane or acetonitrile or dimethylformamide. When the Fmoc group is used, the reagents of choice are piperidine or substituted piperidine in dimethylformamide, but any secondary amine can be used. The deprotection is carried out at a temperature between 0 °C and room temperature (RT). Any of the amino acids having side chain functionalities must be protected during the preparation of

the peptide using any of the above described groups. Those skilled in the art will appreciate that the selection and use of appropriate protecting groups for these side chain functionalities depend upon the amino acid and presence of other protecting groups in the peptide. The selection of such protecting groups is important in that the group must not be removed during the deprotection and coupling of the a-amino group. For example, when Boc is used as the α-amino protecting group, *p*-toluenesulfonyl (tosyl) is suitable to protect the amino side chain of amino acids such as Lys and Arg; acetamidomethyl, benzyl (Bn), or *t*-butylsulfonyl moieties can be used to protect the sulfide containing side chain of cysteine; benzyl (Bn) ethers can be used to protect the hydroxy containing side chains of serine, threonine or hydroxyproline; and benzyl esters can be used to protect the carboxy containing side chains of aspartic acid and glutamic acid. When Fmoc is chosen for the α-amine protection, usually *tert*-butyl based protecting groups are acceptable. For instance, Boc can be used for lysine and arginine, tert-butyl ether for serine, threonine and hydroxyproline, and tert-butyl ester for aspartic acid and glutamic acid. Triphenylmethyl (Trityl) moiety can be used to protect the sulfide containing side chain of cysteine. Once the elongation of the peptide is completed, all of the protecting groups are removed. When a liquid phase synthesis is used, the protecting groups are removed in whatever manner is dictated by the choice of protecting groups. These procedures are well known to those skilled in the art. When a solid phase synthesis is used, the peptide is cleaved from the resin simultaneously with the removal of the protecting groups. When the Boc protection method is used in the synthesis, treatment with anhydrous HF containing additives such as dimethyl sulfide, anisole, thioanisole, or *p*-cresol at 0°C is the preferred method for cleaving the peptide from the resin. The cleavage of the peptide can also be accomplished by other acid reagents such as trifluoromethanesulfonic acid/ trifluoroacetic acid

mixtures. If the Fmoc protection method is used, the N-terminal Fmoc group is cleaved with reagents described earlier. The other protecting groups and the peptide are cleaved from the resin using solution of trifluoroacetic acid and various additives such as anisole, etc.

Synthesis of capping group R^3 and A^6, A^5, A^4, A^3 and A^2 moieties

Different capping groups R^3 are introduced to a protected peptide segment containing a free amino terminus with an appropriate acyl chloride, sulphonyl chloride, or isocyanate that is either available commercially or can be synthesized from methods known in the art. Different A^2 to A^6 amino acids are available commercially or their synthesis is well known in the art. For instance, amino acids may be synthesized in racemic form using the Strecker synthesis or amidomalonate synthesis. In addition, the Myers pseudoephedrine glycinamide alkylation method (Myers, A. G.; Gleason, J. L.; Yoon, T; Kung, D. W.. *J. Am. Chem. Soc.* **1997**, *119*, 656-673) and the Evans electrophilic azidation (Evans, D. A.; Britton, T. C.; Ellman, J. A.; Dorow, R. L. *J. Am. Chem. Soc.* **1990**, *112*, 4011) may be used to prepare unnatural amino acids in enantiomerically pure form. Introduction and manipulation of appropriate protecting groups is well known in the art. Synthesis of substituted prolines are well known in the art. Extensive disclosure of substituted prolines can be found in WO 00/09543 and WO 00/09558 (Llinas-Brunet et al.).

to one skilled in the art (Edwards, P. D.; Bernstein, P. R. *Medicinal Res. Reviews* **1994**, *14*, 127-194, and references cited therein). Scheme 2 shows the synthetic route to α-amino boronic esters **S8** and their peptidyl derivatives. Grignard reagent **S1** is reacted with a trialkyl borate ester **S2**, providing boronate **S3**. Transesterification with (+)-pinanediol **S4** affords the cyclic ester **S5**. This ester ultimately yields enantiomerically pure **S8** with L-configuration. Substitution of pinacol for pinanediol yields racemic product. Homologation of **S5** with the anion of dichloromethane gives the α-chloro boronic ester **S6**

(Matteson, D. S.; Majumdar, D. *Organometallics* **1983**, *2*, 1529-1535). Displacement of chloride by lithium bis(trimethylsilyl)amide gives silyl amine **S7**, which is converted to the amine hydrochloride **S8** with anhydrous HCl (Matteson, D. S., Sadhu, K. M. *Organometallics* **1984**, *3*, 1284-1288). An alternative route to boronate **S3** involves hydroboration of an olefin **S9** with catecholborane **S10** (Brown, H. C.; Gupta, S. K. *J. Am. Chem. Soc.* **1975**, *97*, 5249-5255), providing boronate **S11**, which may be converted to **S8** by the same synthetic sequence as described above for **S3**. Compound **S8** is coupled to a peptide fragment using, for instance, EDCI/HOAt to generate peptide boronic ester **S12**. In some cases, a final step may be required to remove side chain protecting groups on the peptide. (For a general reference to synthesis of peptide boronic esters, see: Kettner, C.; Forsyth, T. *Houben-Weyl Methods of Organic Chemistry* **2000**, in press.)

α-Ketoamides and other electrophilic ketone derivatives are generally introduced in the hydroxy form and oxidized to the active ketone form in the final synthetic step. Scheme 3 illustrates the synthesis of peptidyl α-ketoamides. Other electrophilic ketone derivatives may be prepared analogously (Edwards, P. D.; Bernstein, P. R. *Medicinal Res. Reviews* **1994**, *14*, 127-194, and references cited therein). R^1 substituted acrylate ester **S13** is aminohydroxylated and subsequently deprotected to give amino alcohol **S14**. The amino alcohol is coupled to a peptide fragment to give **S15**. Saponification with LiOH affords acid **S16**, which is coupled to an amine $Y\text{-}NH_2$, to give hydroxy amide **S17**. Oxidation with Dess-Martin periodinane affords the peptidyl α-keto amide **S18.**

UTILITY

The compounds of Formula (I) are expected to inhibit the activity of Hepatitis C Virus NS3 protease. The NS3 protease inhibition is demonstrated using assays for NS3 protease activity, for example, using the assay described below for assaying inhibitors of NS3 protease. Thus, the compounds of Formula (I) are potentially useful in the cure and prevention of HCV infections. Additionally, compounds of the present invention demonstrate unexpected inhibitory selectivity of HCV NS3 protease over elastase inhibition. Additionally, it is expected that compounds of the present invention may show unexpected inhibitory selectivity of HCV NS3 protease over chymotrypsin inhibition.

Biological Activity

Expression and Purification of NS3 Protease

The plasmid cf1SODp600, containing the complete coding region of HCV NS3 protease, genotype 1a, was obtained from ATCC (database accession: DNA Seq. Acc. M62321, originally deposited by Chiron Corporation). PCR primers were designed that allow amplification of the DNA fragment encoding the NS3 protease catalytic domain (amino acids 1 to 192) as well as its two N-terminal fusions, a 5 amino acid leader sequence MGAQH (serving as a expression tag) and a 15 amino acid His tag MRGSHHHHHHMGAQH. The NS3 protease constructs were cloned in the bacterial expression vector under the control of the T7 promoter and transformed in *E. coli* BL 21 (DE3) cells. Expression of the NS3 protease was obtained by addition of 1 mM IPTG and cells were grown for an additional 3 h at 25°C. The NS3 protease constructs have several fold difference in expression level, but exhibit the same level of solubility and enzyme specific activity. A typical 10 L fermentation yielded approximately 200 g of wet cell paste. The cell paste was stored at -80°C. The NS3 protease was purified based on published procedures (Steinkuhler C. et al. *Journal of Virology* 70, 6694-6700, 1996 and Steinkuhler C. et al. *Journal of Biological*

Chemistry 271, 6367-6373, 1996.) with some modifications. Briefly, the cells were resuspended in lysis buffer (10 ml/g) containing PBS buffer (20 mM sodium phosphate, pH 7.4, 140 mM NaCl), 50% glycerol, 10 mM DTT, 2% CHAPS and 1mM PMSF. Cell lysis was performed with use of microfluidizer. After homogenizing, DNase was added to a final concentration 70 U/ml and cell lysate was incubated at 4°C for 20 min. After centrifugation at 18,000 rpm for 30 min at 4°C supernatant was applied on SP Sepharose column (Pharmacia), previously equilibrated at a flow rate 3 ml/min in buffer A (PBS buffer, 10% glycerol, 3 mM DTT). The column was extensively washed with buffer A and the protease was eluted by applying 25 column volumes of a linear 0.14 - 1.0 M NaCl gradient. NS3 containing fractions were pooled and concentrated on an Amicon stirred ultrafiltration cell using a YM-10 membrane. The enzyme was further purified on 26/60 Superdex 75 column (Pharmacia), equilibrated in buffer A. The sample was loaded at a flow rate 1 ml/min, the column was then washed with a buffer A at a flow rate 2 ml/min. Finally, the NS3 protease containing fractions were applied on Mono S 10/10 column (Pharmacia) equilibrated in 50 mM Tris.HCl buffer, pH 7.5, 10% glycerol and 1 mM DTT and operating at flow rate 2 ml/min. Enzyme was eluted by applying 20 column volumes of a linear 0.1 - 0.5 M NaCl gradient. Based on SDS-PAGE analysis as well as HPLC analysis and active site titration, the purity of the HCV NS3 1a protease was greater than 95%. The enzyme was stored at -70°C and diluted just prior to use.

<u>NS3 Protease Enzyme Assays</u>

Concentrations of protease were determined in the absence of NS4a by using the peptide ester substrate Ac-DED(Edans)EEAbuψ[COO]ASK(Dabcyl)-NH_2 (Taliani et al. *Anal. Biochem.* 240, 60-67, 1996.) and the inhibitor, H-Asp-Glu-Val-Val-Pro-boroAlg-OH and by using tight binding reaction

conditions (Bieth, *Methods Enzymol.* 248, 59-85, 1995). Best data was obtained for an enzyme level of 50 nM. Alternately, protease (63 μg/ml) was allowed to react with 3 μM NS4a, 0.10 mM Ac-Glu-Glu-Ala-Cys-*p*NA, and varying level of H-Asp-Glu-Val-Val-Pro-boroAlg-OH (0-6 μM). Concentrations of protease were determined from linear plots of Activity vs. [inhibitor]. Molar concentrations of proteases were determined from the x-intercept. K_m values were determined measuring the rate of hydrolysis of the ester substrate over a range of concentrations from 5.0 to 100 μM in the presence of 3 μM KKNS4a (KKGSVVIVGRIVLSGKPAIIPKK). Assay were run at 25°C, by incubating ~1 nM enzyme with NS4a for 5 min in 148 μl of buffer (50 mM Tri buffer, pH 7.0, 50% glycerol, 2% Chaps, and 5.0 mM DTT. Substrate (2.0 μl) in buffer was added and the reaction was allowed to proceed for 15 min. Reactions were quenched by adding 3.0 μL of 10% TFA, and the levels of hydrolysis were determined by HPLC. Aliquots (50 μL) were injected on the HPLC and linear gradients from 90% water, 10% acetonitrile and 0.1 % TFA to 10% water, 90% acetonitrile and 0.1% TFA were run at a flow rate of 1.0 mL/min over a period of 30 min. HPLCs were run on a HP1090 using a Rainin 4.6 x 250 mm C18 column (cat # 83-201-C) fluorescent detection using 350 and 500 nm as excitation and emission wavelengths, respectively. Levels of hydrolysis were determined by measuring the area of the fluorescent peak at 5.3 min. 100% hydrolysis of a 5.0 μM sample gave an area of 7.95 ±0.38 fluorescence units.). Kinetic constants were determined from the iterative fit of the Michaelis equation to the data. Results are consistent with data from Liveweaver Burk fits and data collected for the 12.8 min peak measured at 520 nm.

Enzyme activity was also measured by measuring the increase in fluorescence with time by exciting at 355 nm and measuring emission at 495 nm using a Perkin Elmer LS 50

spectrometer. A substrate level of 5.0 μM was used for all fluorogenic assays run on the spectrometer.

NS3 Protease Inhibitor Evaluation *In vitro*

Inhibitor effectiveness was determined by measuring enzyme activity both in the presence and absence of inhibitor. Velocities were fit to the equation for competitive inhibition for individual reactions of inhibitors with the enzyme using

$$v_i \,/\, v_o = [K_m\ (1 + I/K_i) + S] \,/\, [K_m + S].$$

The ratio v_i / v_o is equal to the ratio of the Michaelis equations for velocities measured in the presence (v_i) and absence (v_o) of inhibitor. Values of v_i / v_o were measured over a range of inhibitor concentrations with the aid of an Excel™ Spreadsheet. Reported K_i values are the average of 3-5 separate determinations. Under the conditions of this assay, the IC_{50} and K_i's are comparable measures of inhibitor effectiveness.

Compounds tested in the above assay are considered to be active if they exhibit a K_i of ≤50 μM. Preferred compounds of the present invention have K_i's of ≤1 μM. More preferred compounds of the present invention have K_i's of ≤0.1 μM. Even more preferred compounds of the present invention have K_i's of ≤0.01 μM. Still more preferred compounds of the present invention have K_i's of ≤0.001 μM.

Using the methodology described above, compounds of the present invention were found to exhibit a K_i of ≤50 μM, thereby confirming the utility of the compounds of the present invention as effective HCV NS3 protease inhibitors.

NS3 Protease Inhibitor Evaluation of in Cell Assay.

The following method was devised to assess inhibitory action of test compounds on the HCV NS3 protease in cultured cells. Because it is not presently possible to efficiently infect cells with hepatitis C virus, an assay was developed based on co-expression in transfected cell

lines of two plasmids, one is able to direct synthesis of the NS3 protease and the other to provide a polypeptide analogous to a part of the HCV non-structural protein containing a single known peptide sequence highly susceptible to cleavage by the protease. When installed in cultured cells by one of a variety of standard methods, the substrate plasmid produces a stable polypeptide of approximately 50KD, but when the plasmid coding for the viral protease is co-expressed, the enzymatic action of the protease hydrolyzes the substrate at a unique sequence between a cysteine and a serine pair, yielding products which can be detected by antibody-based technology, eg, a western blot. Quantitation of the amounts of precursor and products can be done by scanning film auto-radiograms of the blots or direct luminescense-based emissions from the blots in a commercial scanning device. The general organization of the two plasmids is disclosed in a PCT application PCT/US00/18655. The disclosure of which is hereby incorporated by reference. The coding sequences for the NS3 protease and the substrate were taken from genotype 1a of HCV, but other genotypes, eg 2a, may be substituted with similar results.

The DNA plasmids are introduced into cultured cells using electroporation, liposomes or other means. Synthesis of the protease and the substrate begin shortly after introduction and may be detected within a few hours by immunological means. Therefore, test compounds are added at desired concentrations to the cells within a few minutes after introducing the plasmids. The cells are then placed in a standard CO_2 incubator at 37°C, in tissue culture medium eg Dulbecco-modified MEM containing 10% bovine serum. After 6-48 hours, the cells are collected by physically scraping them from plastic dishes in which they have been growing, centrifuging them and then lysing about 10^6 of the concentrated cells in a minimal volume of buffered detergent, eg 20 μL of 1% sodium dodecyl sulfate in 0.10 M Tris-HCl, pH 6.5, containing 1% mercaptaethanol

and 7% glycerol. The samples are then loaded onto a standard SDS polyacrylamide gel, the polypeptides separated by electrophoresis, and the gel contents then electroblotted onto nitrocellulose or other suitable paper support, and the substrate and products detected by decoration with specific antibodies.

Inhibitory Selectivity

In addition to the inhibitory activity against HCV NS3 protease exhibited by the compounds of Formula (1), Applicants have discovered unexpected benefit of selectivity over inhibition of elastase and/or chymotrypsin proteases. Most HCV NS3 protease inhibitors reported do not show selectivity over elastase. Selectivity of HCV NS3 over elastase can be calculated by dividing IC_{50} (elastase) over IC_{50} (HCV NS3). Similarily, selectivity of HCV NS3 over chymotrypsin can be calculated by dividing IC_{50} (chymotrypsin) over IC_{50} (HCV NS3).

Inhibition Evaluation of Elastase Protease

Human neutrophil elastase was obtained from ART Biochemicals, Athens, Georgia. Stock solutions of lyophilized enzyme (1 mg/ml) were prepared in PBS buffer containing 10% glycerol and stored at -20ºC. Human neutrophil elastase was assayed with the Meo-Suc-Ala-Ala-Pro-Val-p-nitroanilide (Sigma) as a substrate (C. Kettner and A. Shenvi, 1984). The hydrolysis of substrate was monitored at 405 nm on a Hewlett-Packard spectrophotometer. Kinetic parameters were determined in PBS buffer at room temperature with concentration of DMSO did not exceed 2%.

Representative compounds of the present invention have been tested using the assay discussed herein for selectivity over elastase. Table 2 shows unexpected result of inhibitory selectivity of HCV NS3 protease over elastase exhibited by the compounds of the instant invention. In Table 2, NA indicates that inhibition of elastase of the compound was not tested.

Inhibition Evaluation of Chymotrypsin Protease

Human pancreatic chymotrypsin was obtained from Calbiochem, San Diego, California. Stock solutions of lyophilized enzyme (20 uM) were prepared in 1 mM

hydrochloric acid and stored at -20ºC. Human pancreatic chymotrypsin was assayed with the Suc-Ala-Ala-Pro-Phe-p-nitroanilide (Calbiochem cathepsin G substrate #219407) as a substrate. The hydrolysis of substrate was monitored at 405 nm on a Titertek Multiscan MCC/340 plate reader. Kinetic parameters were determined in 0.1 M Tris, pH 7.8, 10 mM $CaCl_2$ buffer at room temperature with a concentration of DMSO that did not exceed 2%.

Although this invention has been described with respect to specific embodiments, the details of these embodiments are not to be construed as limitations. DOSAGE AND FORMULATION

The HCV protease inhibitor compounds of this invention can be administered as treatment for the control or prevention of hepatitis C virus infections by any means that produces contact of the active agent with the agent's site of action, i.e., the NS3 protease, in the body of a mammal. It can be administered by any conventional means available for use in conjunction with pharmaceuticals, either as an individual therapeutic agent or in a combination of therapeutic agents. It can be administered alone, but preferably is administered with a pharmaceutical carrier selected on the basis of the chosen route of administration and standard pharmaceutical practice.

The compounds of the present invention can be administered in such oral dosage forms as tablets, capsules (each of which includes sustained release or timed release formulations), pills, powders, granules, elixirs, tinctures, suspensions, syrups, and emulsions. Likewise, they may also be administered in intravenous (bolus or infusion), intraperitoneal, subcutaneous, or intramuscular

form, all using dosage forms well known to those of ordinary skill in the pharmaceutical arts.

The dosage administered will, of course, vary depending upon known factors, such as the pharmacodynamic characteristics of the particular agent and its mode and route of administration; the age, health and weight of the recipient; the nature and extent of the symptoms; the kind of concurrent treatment; the frequency of treatment; and the effect desired. By way of general guidance, a daily dosage of active ingredient can be expected to be about 0.001 to about 1000 milligrams per kilogram of body weight, with the preferred dose being about 0.01 to about 100 mg/kg; with the more preferred dose being about 0.1 to about 30 mg/kg. Advantageously, compounds of the present invention may be administered in a single daily dose, or the total daily dosage may be administered in divided doses of two, three, or four times daily.

Dosage forms of compositions suitable for administration contain from about 1 mg to about 100 mg of active ingredient per unit. In these pharmaceutical compositions the active ingredient will ordinarily be present in an amount of about 0.5-95% by weight based on the total weight of the composition. The active ingredient can be administered orally in solid dosage forms, such as capsules, tablets and powders, or in liquid dosage forms, such as elixirs, syrups and suspensions. It can also be administered parenterally, in sterile liquid dosage forms.

Gelatin capsules contain the active ingredient and powdered carriers, such as lactose, starch, cellulose derivatives, magnesium stearate, stearic acid, and the like. Similar diluents can be used to make compressed tablets. Both tablets and capsules can be manufactured as sustained release products to provide for continuous release of medication over a period of hours. Compressed tablets can be sugar coated or film coated to mask any unpleasant taste and protect the tablet from the atmosphere, or enteric coated for selective disintegration

in the gastrointestinal tract. Liquid dosage forms for oral administration can contain coloring and flavoring to increase patient acceptance.

In general, water, a suitable oil, saline, aqueous dextrose (glucose), and related sugar solutions and glycols such as propylene glycol or polyethylene glycols are suitable carriers for parenteral solutions. Solutions for parenteral administration preferably contain a water soluble salt of the active ingredient, suitable stabilizing agents, and if necessary, buffer substances. Antioxidizing agents such as sodium bisulfite, sodium sulfite, or ascorbic acid, either alone or combined, are suitable stabilizing agents. Also used are citric acid and its salts, and sodium EDTA. In addition, parenteral solutions can contain preservatives, such as benzalkonium chloride, methyl- or propyl-paraben and chlorobutanol. Suitable pharmaceutical carriers are described in *Remington's Pharmaceutical Sciences*, *supra*, a standard reference text in this field.

Useful pharmaceutical dosage-forms for administration of the compounds of this invention can be illustrated as follows:

<u>Capsules</u>

A large number of unit capsules can be prepared by filling standard two-piece hard gelatin capsules each with 100 mg of powdered active ingredient, 150 mg of lactose, 50 mg of cellulose, and 6 mg magnesium stearic.

<u>Soft Gelatin Capsules</u>

A mixture of active ingredient in a digestible oil such as soybean oil, cottonseed oil or olive oil can be prepared and injected by means of a positive displacement pump into gelatin to form soft gelatin capsules containing 100 mg of the active ingredient. The capsules should then be washed and dried.

Tablets

A large number of tablets can be prepared by conventional procedures so that the dosage unit is 100 mg of active ingredient, 0.2 mg of colloidal silicon dioxide, 5 milligrams of magnesium stearate, 275 mg of microcrystalline cellulose, 11 mg of starch and 98.8 mg of lactose. Appropriate coatings may be applied to increase palatability or delay absorption.

Suspension

An aqueous suspension can be prepared for oral administration so that each 5 ml contain 25 mg of finely divided active ingredient, 200 mg of sodium carboxymethyl cellulose, 5 mg of sodium benzoate, 1.0 g of sorbitol solution, U.S.P., and 0.025 mg of vanillin.

Injectable

A parenteral composition suitable for administration by injection can be prepared by stirring 1.5% by weight of active ingredient in 10% by volume propylene glycol and water. The solution is sterilized by commonly used techniques.
